

Like a factory, the job of the factory method is to create -- or manufacture -- objects.

The objective of factory method pattern is:

1. There might be scenarios where object creation is scattered and repetitive in various parts of the code. This pattern avoids that.
2. Client need to know/worry about the objection creation logic.
3. Client should access the objects through a common interface.

```
public abstract class Person {
    protected final String name;
    public Person(String name) {
        this.name = name;
    }
}

public class Male extends Person {
    public Male(String name) {
        super(name);
    }
}

public class Female extends Person {
    public Female(String name) {
        super(name);
    }
}

public class PersonFactory
{
    public static Person makePerson(String gender, String name)
    {
        if(gender.equals("male"))
        {
            Male man=new Male(name);
            return man;
        }
        else
        {
            Female woman=new Female(name);
            return woman;
        }
    }
}
```
